ABSTRACT

This thesis investigates the linear state space modeling of a tiltrotor aircraft by modifying an existing MATLAB routine which is used for preliminary (helicopter) stability and control analysis. The modifications consist of changing existing script files along with adding new ones. The modifications result in having a routine that allows the input of tiltrotor characteristics and subsequently generates a state space model along with other stability and control characteristics. The tiltrotor modeling is validated by the input of XV-15 characteristic data into the program and performing an eigenvalue comparison with a model of a similar tiltrotor, the V-22. A more extensive comparison is performed with another XV-15 model which has been extensively used and validated with wind tunnel and flight tests.

θ_{oT}	thetaot	Tail rotor pitch or Yaw input (tiltrotor equivalent to) (actually ΔB_1 or $B_{1(right)} = -B_{1(left)}$)	radians

ACKNOWLEDGMENTS

I wish to give thanks to a number of individuals who have unselfishly supported my research on this thesis. To Dr. Bob Wood, a superb advisor to me not only for my thesis, but also toward my future endeavors in the rotorcraft industry. To Sam Ferguson, for his seemingly limitless knowledge of tiltrotor modeling and simulation (and willingness to share some of it to me). I would especially like to thank him for all the uncompensated time he devoted to getting the data I requested for which I could not have done it without his help.

I would like to give my deepest thanks to my loving wife, Traci, and her family for their continued encouragement and undying support throughout my extended time here. Finally, to my daughters, Jessie and Morgan, who without them and their mother to come home to every day, all this would not have been so important. We're finally done!

I. INTRODUCTION

A. TILTROTOR --- HELICOPTER OR AIRPLANE?

The first truly successful tiltrotor aircraft to be flown and fully tested was the Bell/NASA XV-15. It demonstrated the hover advantages of a helicopter and the speed advantages of a fixed wing aircraft. Since then, there have been many aircraft requirements that could use these advantages. In designing such an aircraft, the problem of predicting the flying qualities is an important part of the process. Helicopter aerodynamics are in themselves very complicated and are often shunned by the aerodynamicist, but a tiltrotor is not only a helicopter, it is an airplane too.

There are two primary modes of flight that are most important in the dynamic analysis, namely helicopter and airplane modes. These are the most important flight modes because they are the ones in which the aircraft spends the majority of its time. In the helicopter mode, the rotors (shafts) are pointed vertically up. In this mode, the aircraft flies like a helicopter, meaning normal "helicopter" flight control movements result in normal "helicopter" type responses. The airplane mode is where the rotors are pointed forward, and the aircraft flies like a normal airplane.

B. BACKGROUND

The Helicopter Design course at the Naval Postgraduate School has been using software called JANRAD developed by students to assist in the preliminary design of rotorcraft. This software (short for Joint Army-Navy Rotorcraft Analysis and Design) is a series of Matlab script files that takes in physical and aerodynamic characteristics of a helicopter and then generates a performance, stability and control analysis on the input aircraft. This past year's design course was given design requirements that were better served by a tiltrotor. The JANRAD software, however, is geared to analyze a helicopter (or compound helicopter) and can only be used to analyze a tiltrotor with modifications. This project covers the modifications that are necessary to accurately model the dynamics of a tiltrotor aircraft.

C. WHAT IS A TILTROTOR ?

Before the dynamics of an aircraft can be discussed, a physical description of the aircraft, including its flying characteristics, is needed. In this description, the reader is assumed

to have working knowledge of basic helicopter and airplane dynamics and the associated engineering terminology of both types of aircraft.

In the helicopter mode, the aircraft's rotor dynamics produce the primary forces. Therefore, the design of the rotor head must be examined. The XV-15 and V-22 have very similar rotor head designs. Compared to a helicopter design, they have three blades on a gimbaled head, which is essentially a teetering three bladed rotor (or proprotor as the tiltrotor community calls them). With this design, there is no flapping hinge offset, and each blade's flapping is affected by the gimbal hinge (like a ball and socket joint). The right rotor rotates in the same direction as a conventional (U.S.) helicopter, which is counter clockwise (CCW) as viewed from above the aircraft. The left rotor rotates in the opposite direction to counter the torque of the right rotor.

The proprotor blades differ from a conventional helicopter blade in that they are highly twisted (~ 40 degrees compared to ~10 degrees for a helicopter). This design is a compromise between hover performance which favors slightly twisted blades and forward flight performance (in the airplane mode) which desires the twist to be more like an airplane propeller (~ 60 degrees). Also unlike a helicopter blade, the proprotor blades have variable thickness and taper.

The control of a tiltrotor is the most interesting aspect of the design. Since the analysis will be broken down into two distinct modes -- Helicopter and Airplane, the control dynamics should be too. They are depicted in Figure 1.1. In helicopter mode, the rotor shafts are pointed upward as a conventional helicopter with zero incidence angle. Longitudinal control (cyclic) is essentially made the same way as a helicopter by tilting each swashplate longitudinally. Like a helicopter, this swashplate movement induces cyclic feathering which in turn produces longitudinal flapping. Also the same as a conventional helicopter is collective control. The collective simply moves the swashplates (each in equal amounts) up and down the rotor shaft, which in turn produce more or less pitch on the blades.

Lateral/directional control is where the real difference comes in. First, lateral cyclic, or rolling control, in a tiltrotor is made through differential collective inputs on each rotor. Lateral cyclic produce equal and opposite swashplate movement along the rotor shafts, producing equal and opposite forces on either sides of the aircraft. Although there is some lateral swashplate movement in the V-22, it is not produced by lateral cyclic. Lateral swashplate movement is for lateral cyclic trim for trimming a roll angle for (sideward) sloped landings or for allowing a level fuselage angle for high crosswind approach/landing conditions. This trim is not directly affected

Figure 1.1 Helicopter and Airplane Controls

by lateral control movement, but instead by a trimming thumbwheel on the control stick, which results in the movement of the rotors depicted in Figure 1.1 as the Lateral Translational Mode. Next, directional control is made through differential longitudinal swashplate tilting, which

produces a tilting of the thrust vector equal and opposite to the other proprotor head. This produces a yawing moment to facilitate heading changes with the application of the directional pedals.

The airplane mode flight controls are not as interesting or unique. As with most conventional airplanes, longitudinal control is produced through movement of the elevator on the horizontal stabilizer (H-stab). This control input directly produces a pitching moment, M , and indirectly changes the speed of aircraft in trim. The power input in a tiltrotor changes the proprotor thrust, directly changing the speed of the aircraft and indirectly changing the altitude of the aircraft in trim. Lateral control is made through the differential movement of ailerons on the ends of the wing, causing a rolling moment, R . Finally, directional control in the tiltrotor is made through the movement of rudders, as in any twin rudder airplane.

II. SOFTWARE OVERVIEW

A. ORIGINAL SOFTWARE ARCHITECTURE

JANRAD consists of two major subroutines which are applicable to this project. The first routine, JANRAD Performance, calculates the trim solution and various performance parameters of a helicopter. It is described in detail in Ref. 9. The second one is the JANRAD Stability and Control routine shown in Figure 2.1, and the details of this routine are described in

Figure 2.1 JANRAD Architecture

Reference 7. The second will be the main focus of the modifications presented in this project. In this chapter, "JANRAD" will refer to the older version that is to be modified.

The opening menu for JANRAD has the user enter data for performance calculations. If data has already been entered but some need to be modified, it has the following modification menu shown in Figure 2.2. This menu allows for changing all the input parameters needed for the helicopter performance calculations. This set of data is incomplete for stability and control analysis of a tiltrotor. Therefore, an additional set of input menus was developed in order to permit the more detailed data to be entered or changed. A description of these new menus appears in Section C following.

```

```

Figure 2.2 JANRAD Main Edit Menu Screen

Once the proper data has been entered, a set of performance calculations must precede the stability calculations in the model. This is because they are based on trimmed flight control positions, and these positions can only be determined through an extensive performance/trim routine. For the helicopter in either hover or forward flight, the trimming involves determining the swashplate position equating to collective pitch (θ_{0M}), longitudinal and lateral flapping angles (a_{1s} and b_{1s} respectively) and (for a conventional helicopter) the collective pitch (θ_{0T}) of the tail rotor. When these are determined, the stability analysis calculations can proceed.

B. MODELING CONVENTIONS

The basic aircraft model and modeling conventions of JANRAD are presented here. The coordinate system used in modeling the aircraft is the conventional NACA orthogonal aircraft axis system, where the x-axis runs along the longitudinal axis (directed toward the front) of the aircraft. The y-axis is directed toward the right wing, and the z-axis is perpendicular to x and y, directed downward to the ground. The locations of aircraft components are referenced to a datum position where the fuselage station is the (x) distance aft of the longitudinal datum, buttline is the (y) position right of fuselage centerline and waterline is the vertical location above the (z) datum point.

The simplified dynamic model is nonlinear, meaning the equations of motion are written as a set of nonlinear differential equations. They are a series of three force (one for each axis) and three moment equations. The moment equations were integrated to produce a total of nine equations for this model. These equations were then linearized by using small perturbations about a trimmed (steady-state) condition, retaining the first term of the Taylor Series expansion for each relation. This linearization produces a set of nine constant coefficient, linear differential equations which are expressed in the standard state space format of a matrix differential equation, $\dot{\mathbf{x}} = [\mathbf{A}]\mathbf{x} + [\mathbf{B}]\mathbf{u}$, where the elements in the state vector \mathbf{x} represent the perturbations from the trimmed value in the following order:

$$\mathbf{x} = \begin{bmatrix} u_B \\ w_B \\ q_B \\ \theta_B \\ v_B \\ p_B \\ \Phi_B \\ r_B \\ \Psi_B \end{bmatrix} \begin{array}{ll} \text{velocity of the aircraft in the positive x direction} & (\text{ft/sec}) \\ \text{velocity of the aircraft in the positive z direction} & (\text{ft/sec}) \\ \text{pitch rate of the aircraft (about the positive y - axis)} & (\text{rad/sec}) \\ \text{pitch angle of the aircraft " " " "} & (\text{radians}) \\ \text{velocity of the aircraft in the positive y direction} & (\text{ft/sec}) \\ \text{roll rate of the aircraft (about the positive x - axis)} & (\text{rad/sec}) \\ \text{roll angle of the aircraft " " " "} & (\text{radians}) \\ \text{yaw rate of the aircraft (about the positive z - axis)} & (\text{rad/sec}) \\ \text{yaw angle of the aircraft " " " "} & (\text{radians}) \end{array} \quad (2.1)$$

The first four states are classified as the longitudinal states and the final five are the lateral-directional states. These classifications are used when it is desired to reduce the model to two "uncoupled" state models.

The elements in the control vector \mathbf{u} , shown below, represent the perturbations in the corresponding feathering of the rotor blades from each of the trimmed control positions.

$$\mathbf{u} = \begin{bmatrix} \delta_{B_1} \\ \delta_{\theta_0} \\ \delta_{A_1} \\ \delta_p \end{bmatrix} \begin{array}{l} \text{longitudinal cyclic (positive aft)} \\ \text{collective pitch . . . (positive up)} \\ \text{lateral cyclic . . . (positive right)} \\ \text{directional pedal (positive right)} \end{array} \quad (2.2)$$

The final control vector used in the model is converted to inches of stick/pedal movement by applying the flight control rigging relationships. The first two inputs produce predominately longitudinal responses, and the second two inputs produce lateral-directional ones.

The [A] matrix contains the resulting coefficients from the Taylor Series first order approximation. These coefficients are simply partial derivatives commonly referred to as the stability derivatives of the aircraft. The stability derivatives make up the [A] matrix as shown in Appendix B. This format is taken from NASA Technical Memorandum 84281 [Ref. 8], which also includes some derivations of the relations used.

C. SOFTWARE MODIFICATIONS AND ADDITIONS

Because a tiltrotor's flying qualities differ significantly from those of a helicopter, there are different aircraft parameters that affect how the aircraft behaves when perturbed from a trimmed state. Most parameters recorded in JANRAD are the same as those affecting the behavior of a tiltrotor in the hover mode. However, the tiltrotor's dynamics in the airplane mode are affected by parameters not recorded by JANRAD, and it is for this reason that JANRAD's stability input routine, STAB.M, had to be modified. These modifications were made with the fewest number of changes to the routine as possible resulting in JANRAD routines being both modified and augmented by new routines to facilitate the necessary functions. The significantly modified routines are listed in Appendix L and the routines that were written and added to JANRAD are in Appendix M.

As discussed previously, a tiltrotor is similar to a helicopter in the hover mode. The major differences occur in its airplane-like characteristics in the cruise mode. Therefore, in the hover mode, the parameters that JANRAD's stability section uses in its analysis almost suffice for a tiltrotor. The only additional parameter that affects the hover mode dynamics is the addition of a flapping spring constant. Because the tiltrotors have gimbaled rotor heads, their

flapping is constrained by centrifugal force and (in some designs) also by a flapping spring which produces significant moments when the blades flap. The first modification is the addition of a flapping spring constant (#6) in the additional parameters change menu screen 1, shown in Figure 2.3.

0. NO CHANGES

Input the parameter to change:

```

Figure 2.3 Modified Additional Parameters Change Menu Screen 1

The airplane characteristics are where the majority of the modifications and additions come in. JANRAD's stability routine does take into account some wing and fuselage parameters but not enough to sufficiently describe the dynamics of an airplane. Menu screen 1 of the existing JANRAD shows vertical tail parameters significant in a tiltrotor, but it also needs rudder effectiveness (#24) to be added for the airplane mode control derivatives. These two modifications complete those needed on screen #1.

In order to accommodate additional parameters without adding a new screen, the CG information was moved from menu screen 3 to screen 2, as shown in Figure 2.4. This freed up space on menu screen #3 to add a tiltrotor section and some rigging parameters for an airplane. These additional parameters are shown in Figure 2.5. All of these new parameters were also added to the section of STAB.M which inputs the data from scratch.

```

The final modification for STAB.M is to provide the management software for calling separate routines that perform the tiltrotor analysis. Because the dynamics of the tiltrotor and a helicopter differ so much, the routines that calculate the stability derivatives, HOVER and CRUISE, needed to be modified significantly. These major modifications made it impractical to use the same routines for both a helicopter and a tiltrotor. Therefore, new ones were written for both flight regimes. These are HTLTRGRP.M, to calculate the hover mode stability derivatives themselves, and TLTRHOVR.M, to put the derivatives in the state-space equations/matrices. Similarly, CTLTRGRP.M and TLTRCRUS.M were written for the airplane mode. The development of the equations which make up these routines will be discussed in Chapter III.

The output routines contain the final modifications made to JANRAD. STABOUT.M is the primary output routine for JANRAD's stability section, which calls many other subroutines to perform plotting and other functions. The obvious modification is the addition of the tiltrotor parameters for the input data summary and the airplane type calculated data not present in the helicopter analysis. This routine was written a few years ago and there have been later refinements in MATLAB which make some additional modifications desirable (and in some instances necessary) to run the program with the latest version of MATLAB (version 4.2c). The old STABOUT.M printed the plots to a file using the META command which Matlab's latest version no longer uses. The necessary modification made was in the method of saving and/or printing the many plots generated. STABOUT.M now saves all plots in the Windows Metafile (xxx.wmf) format to be printed using the user's preferred word processor.

One of the key outputs of the JANRAD Stability section is the set of command bandwidth plots. These are simply Bode magnitude plots for all the control inputs to their respective desired outputs. Some important analyses can be made with this data, and with the modifications made to the plot statements these plotting routines should still be a part of the output. However, with the greater interest in time domain analysis in today's stability and control world, frequency domain analysis alone (exemplified by these command bandwidth plots) does not suffice. Incorporating some time domain analysis in this program is relatively painless, especially with Matlab. The structure of the Bode plot routines could be used with the BODE commands being replaced with LSIM commands to give time responses to appropriate control inputs. Most helicopter control inputs produce rate responses in the open-loop case (which this analysis considers). Therefore, simple step inputs would not give favorable responses. The more appropriate responses to be observed would be short time pulses for the

longitudinal inputs and doublets for the lateral/directional ones. Doublets should be used because the net control input is zero which keeps the aircraft from entering a turn.

D. TRIMMING ROUTINES

The old JANRAD trimming routine, TRIM, had to be renamed because it conflicted with the Matlab command of the same name. This routine is used by the performance section of JANRAD, as well as the stability and control section. Ref. 9 goes into detail on the methods used to trim the helicopter controls, but these methods did not work well for the tiltrotor. Trimming a tiltrotor in the helicopter mode is somewhat different than trimming a conventional helicopter and is completely different from the trimming the aircraft in the airplane mode. Therefore, new trimming routines for both modes had to be constructed.

First, the helicopter mode trimming routine was modified to accommodate a tiltrotor as well as a conventional helicopter. These changes were primarily designed to remove the tail rotor trimming portion. Therefore, the only trimming parameters that are needed are the collective and the longitudinal cyclic swashplate positions. Longitudinal cyclic is only required for forward flight speeds, so if hover is the only mode which is being analyzed, collective trim is the only parameter to be determined. The old code as well as a routine with the above mentioned modifications (developed apart from this project) were evaluated for the hover mode and the trim results were not acceptably close to the results of Ref. 4. Therefore, the trim values of Ref. 4. were inserted by a script file in order to have comparable trim conditions to start with in determining the stability and control derivatives.

Airplane mode trim is a completely different and much less complicated procedure. In the airplane mode, the flight control positions for straight and level flight are the power (thrust) control and the longitudinal (elevator) control. These positions would simply be determined by balancing out the force and the moment equations. The two equations have the elevator position (δ_e) and wing angle of attack (α_w) as the two unknowns, and they can be determined using a linear technique.

The dominant forces of the tiltrotor used to determine trim in airplane mode are the lift of the three major lifting surfaces. In the following discussion, the standard lift coefficient relationship is used where the lift coefficient, C_L is the lift of the lifting body divided by the dynamic pressure, q and the reference area, A . The lift coefficient is typically a linear relationship with the angle of attack, α and the lift curve slope, C_{L_α} or "a" such that $C_L = C_{L_\alpha} \alpha$.

Continuing with these relationships, the following force equations use the standard aerodynamic lift relationship, $L = qAC_L = qAC_{L_\alpha}\alpha = qAa\alpha$ for each lifting surface:

$$\Sigma F=0 \rightarrow GW = L_{\text{wing}} + L_{\text{fuselage}} + L_{\text{H-stab}} \quad (2.3)$$

$$L_{\text{wing}} = qA_w[a_w(\alpha_w - \alpha_{ol}) + \frac{\partial C_{l(\text{flap})}}{\partial \delta_{\text{flap}}} \delta_{\text{flap}}] \quad (2.4)$$

$$L_{\text{H-stab}} = q_H A_H(a_H \alpha_H + \frac{\partial C_{l_H}}{\partial \delta_e} \delta_e) \quad (2.5)$$

$$\text{where, } \alpha_H = \alpha_w - i_w + i_H - \varepsilon \quad (2.6)$$

$$\text{and, } \varepsilon = \varepsilon_0 + \frac{\partial \varepsilon}{\partial \alpha}(\alpha_w - \alpha_{ol_w} + \frac{\partial C_{l(\text{flap})}}{\partial \delta_{\text{flap}}} \frac{\delta_{\text{flap}}}{a_w}) \quad (2.7)$$

$$\begin{aligned} L_{\text{fuselage}} &= qA_w C_{l_f} = qA_w a_f(\alpha_f - \alpha_{ol_f}) \text{ where } \Rightarrow \alpha_f = \alpha_w - i_w \\ &= qA_w a_f(\alpha_w - i_w - \alpha_{ol_f}) \end{aligned} \quad (2.8)$$

These forces must balance out to zero for the aircraft to trim in flight. The resulting force equation, with the unknowns α_w and δ_e accessible, is arranged as follows:

$$\begin{aligned} &\underbrace{q[A_w(a_w + a_f) + \frac{q_H}{q} a_H A_H(1 - \frac{\partial \varepsilon}{\partial \alpha})]}_{\frac{\partial L}{\partial \alpha}} \alpha_w + \underbrace{(q \frac{q_H}{q} A_H a_H \frac{\partial C_{l_H}}{\partial \delta_e})}_{\frac{\partial L}{\partial \delta_e}} \delta_e = \\ &\underbrace{GW + q\{A_w[a_w \alpha_{ol_w} + a_f(i_w + \alpha_{ol_f})] - \frac{q_H}{q} A_H a_H(i_H - i_w - \varepsilon_0)\}}_{L_{tr}} \end{aligned} \quad (2.9)$$

The moments must also balance out. Many of the moments are simply the forces in the force equation creating moments due to their relative distances from the center of gravity. These moments are combined with the aerodynamic moments to form the following moment equations. As with the lift equations, they use the moment coefficient similar to its lift counterpart with the addition of a reference chord length, c to non-dimensionalize the coefficient. The moment coefficient, C_M is defined as the lifting surface moment, M divided (again, as with the lift coefficient) by q and A but also by c . This results in the standard aerodynamic moment relationship, $M = qAcC_M$ for each lifting surface. C_M is also typically a linear relationship with

α such that $C_M = C_{M\alpha}\alpha + C_{M0}$. The following are the remaining equations used to trim the aircraft:

$$\Sigma M=0 \rightarrow M_{wing} + M_{fuselage} + M_{H-stab} = 0 \quad (2.10)$$

$$M_{wing} = qA_w c_w (C_{mo_w} + C_{m\alpha_w} \alpha_w) - l_w L_w \quad (2.11)$$

$$M_{H-stab} = -l_H L_H \quad (2.12)$$

$$M_{fuselage} = qA_w c_w (C_{mo_f} + C_{m\alpha_f} \alpha_f) \quad (2.13)$$

$$\Sigma M = qA_w c_w (C_{mo_w} + C_{mo_f} + C_{m\alpha_f} \alpha_f) - l_w L_w - l_H L_H - l_f L_f \quad (2.14)$$

Substituting in for the lift terms and rearranging so the two unknowns are accessible leads to:

$$\underbrace{qA_w [c_w C_{m\alpha_f} - l_w a_w - l_f a_f - l_H \frac{q_H}{q} a_H \frac{A_H}{A_w} (1 - \frac{\partial \epsilon}{\partial \alpha})]}_{\frac{\partial M}{\partial \alpha_w}} \alpha_w - \underbrace{(q \frac{q_H}{q} A_H a_H l_H \frac{\partial C_{l_H}}{\partial \delta_e})}_{\frac{\partial M}{\partial \delta_e}} \delta_e = \quad (2.15)$$

$$\underbrace{q \{ A_w [c_w (C_{m\alpha_f} i_w - C_{mo_w} - C_{mo_f}) - l_w a_w \alpha_{ol_w}] - l_f a_f (i_w + \alpha_{ol_f}) + l_H \frac{q_H}{q} A_H a_H (i_H - i_w - \epsilon_0) \}}_{M_{tr}}$$

Combining the force and the moment equations gives the following matrix equation in α_w and δ_e .

$$\left\{ \begin{array}{l} \frac{\partial L}{\partial \alpha_w} \alpha_w + \frac{\partial L}{\partial \delta_e} \delta_e = L_{tr} \\ \frac{\partial M}{\partial \alpha_w} \alpha_w + \frac{\partial M}{\partial \delta_e} \delta_e = M_{tr} \end{array} \right\} \Rightarrow \begin{bmatrix} \frac{\partial L}{\partial \alpha_w} & \frac{\partial L}{\partial \delta_e} \\ \frac{\partial M}{\partial \alpha_w} & \frac{\partial M}{\partial \delta_e} \end{bmatrix} \begin{bmatrix} \alpha_w \\ \delta_e \end{bmatrix} = \begin{bmatrix} L_{tr} \\ M_{tr} \end{bmatrix} \quad (2.16)$$

All of these force and moment equations are incorporated in the routine, APTRIM.M listed in Appendix M.

III. DEVELOPMENT OF STABILITY DERIVATIVES

A. HELICOPTER MODE

The focus of this project is the development of the stability derivatives that make up the state space model for the aircraft. Before this development can be discussed, the underlying assumptions must be highlighted. Since this project is a modification to JANRAD (helicopter) routines, the assumptions used in its original development are listed below.

1. The aircraft is a rigid body (including the rotor blades).
2. Small climb angles, pitch attitudes, and angles of attack.
3. Linearity in all derivatives and partial derivatives (first order Taylor Series approximation)
4. Constant or average lift curve slope for the proprotor blades.
5. Uniform inflow through rotor system.
6. Aircraft out of ground effect.

Additional assumptions were also made for the tiltrotor with respect to its helicopter mode analysis. These assumptions are summarized below.

1. The two proprotors behave like two counter-rotating helicopter rotor heads.
2. Right proprotor rotates CCW (as viewed from the top) and left, CW.
3. Airframe out of rotor wake influence.

The approach this analysis takes is to use the equations in Ref. 6 and Ref. 7 where they apply and modify them where they do not. The first set of derivatives are the basic hover derivatives. As discussed in References 6 and 7, these are subsequently used in the stability derivatives themselves. Some of these derivatives have opposite signs if the rotational direction of the rotor system is CW. Therefore, a careful study of the sign convention of each term was made. So that the derivatives for each proprotor head have a consistent sign, the convention for the flapping angles are such that $a_{1s(\text{left})} = a_{1s(\text{right})}$ and $b_{1s(\text{left})} = -b_{1s(\text{right})}$. With this convention, the basic rotor derivatives in Ref. 6 can be used. These derivatives are depicted in Table 3.1.

Another set of convention used in this analysis is one for the lateral/directional inputs. The JANRAD helicopter section (along with Ref. 6) uses the notation of A_1 (or $\frac{\partial(\cdot)}{\partial A_1}$ for its lateral derivatives) where A_1 is the lateral swashplate angle. However, as discussed in Chapter II, roll inputs are made with a tiltrotor by having differential collective on each rotor. For consistency, the tiltrotor lateral derivatives will use the same notation as the helicopter section for this analysis even though there is no true lateral feathering, A_1 with a tiltrotor. Similarly for directional inputs, the notation, θ_{or} (as in $\frac{\partial(\cdot)}{\partial \theta_{or}}$) is used in the code but for clarity, $\frac{\partial(\cdot)}{\partial \delta_p}$ and $\frac{\partial(\cdot)}{\partial \Delta B_1}$ are used interchangeably in the discussion because they are more descriptive for a tiltrotor directional pedal input.

Basic Rotor Derivatives

$$\frac{\partial \mu}{\partial \dot{x}}, \frac{\partial \lambda'}{\partial \dot{z}} = \frac{1}{\Omega R}$$

$$\frac{\partial a_{1s}}{\partial \mu} = \frac{8}{3}\theta_o + 2\theta_1 - 2\frac{v_1}{\Omega R}$$

$$\frac{\partial b_{1s}}{\partial \mu} = \frac{4}{3}a_o$$

$$\left\{ \begin{array}{l} \frac{\partial C_{T/\sigma}}{\partial \theta_o} \\ \frac{\partial C_{Q/\sigma}}{\partial \theta_o} \end{array} \right\} \quad \text{Calculated numerically in the Performance Section}$$

$$\frac{\partial C_{T/\sigma}}{\partial \lambda'} = \left(\frac{8}{a} + \frac{\sqrt{\sigma/2}}{\sqrt{C_{T/\sigma}}} \right)^{-1}$$

$$\frac{\partial C_{Q/\sigma}}{\partial \lambda'} = -\frac{a}{4} \left(\theta_{.75} - 2\frac{v_1}{\Omega R} \right)$$

$$\left(\frac{\partial a_{1s}}{\partial p} \right)_R = - \left(\frac{\partial a_{1s}}{\partial p} \right)_L, \quad - \left(\frac{\partial b_{1s}}{\partial q} \right)_R = \left(\frac{\partial b_{1s}}{\partial q} \right)_L = \frac{1}{\Omega} \left[1 - \frac{192 \left(\frac{e}{R} \right)}{\gamma^2 \left(1 - \frac{e}{R} \right)^5} \right]$$

$$\left(\frac{\partial a_{1s}}{\partial q}, \frac{\partial b_{1s}}{\partial p} \right)_R = \left(\frac{\partial a_{1s}}{\partial q}, -\frac{\partial b_{1s}}{\partial p} \right)_L = -\frac{16}{\gamma \Omega \left(1 - \frac{e}{R} \right)^2} - \frac{12 \left(\frac{e}{R} \right)}{\gamma \Omega \left(1 - \frac{e}{R} \right)^3}$$

Continued

Table 3.1

Basic Rotor Derivatives (continued)

Table 3.1 (continued)

1. Force Derivatives

Due to the counter rotating effect, many derivatives are the same for each propotor head, and others are equal but opposite in sign. With the force derivatives, this phenomena causes the derivatives with the same sign to be additive and the ones of opposite sign to cancel each other.

a. X-Force Derivatives

An example of the additive effect is the X-force perturbation with respect to a small perturbation in forward velocity, or $\left(\frac{\partial X}{\partial \dot{x}} \right)_{\text{total}}$, is simply twice the effect of each rotor alone. The negating effect is demonstrated by the in sideward velocity derivative, $\left(\frac{\partial X}{\partial \dot{y}} \right)_{\text{total}}$. Here, due to the proprotors rotating in opposite directions, the right derivative is equal in magnitude to the one for the left side but of opposite sign. Therefore, the resulting force derivative is zero, as shown in Table 3.2.

X-force Derivatives

Development

(=>) Derivative

$$\begin{aligned} \left(\frac{\partial X}{\partial \dot{x}}\right)_{\text{right}} &= \left(\frac{\partial X}{\partial \dot{x}}\right)_{\text{left}} = -\rho A_b (\Omega R)^2 \left(\frac{\partial C_{H/\sigma}}{\partial a_{1s}}\right) \left(\frac{\partial a_{1s}}{\partial \mu}\right) \left(\frac{\partial \mu}{\partial \dot{x}}\right) \\ &\Rightarrow \left(\frac{\partial X}{\partial \dot{x}}\right)_{\text{total}} = -2\rho A_b (\Omega R)^2 \left(\frac{\partial C_{H/\sigma}}{\partial a_{1s}}\right) \left(\frac{\partial a_{1s}}{\partial \mu}\right) \left(\frac{\partial \mu}{\partial \dot{x}}\right) \end{aligned}$$

$$\left(\frac{\partial X}{\partial \dot{y}}\right)_{\text{right}} = -\left(\frac{\partial X}{\partial \dot{y}}\right)_{\text{left}} \Rightarrow \left(\frac{\partial X}{\partial \dot{y}}\right)_{\text{total}} = 0$$

$$\left(\frac{\partial X}{\partial p}\right)_{\text{right}} = -\left(\frac{\partial X}{\partial p}\right)_{\text{left}} \Rightarrow \left(\frac{\partial X}{\partial p}\right)_{\text{total}} = 0$$

$$\left(\frac{\partial X}{\partial q}\right)_{\text{right}} = -\left(\frac{\partial X}{\partial q}\right)_{\text{left}} \Rightarrow \left(\frac{\partial X}{\partial q}\right)_{\text{total}} = 0$$

*** Control Inputs ***

$$\begin{aligned} \left(\frac{\partial X}{\partial \theta_o}\right)_{\text{right}} &= \left(\frac{\partial X}{\partial \theta_o}\right)_{\text{left}} \\ &\Rightarrow \left(\frac{\partial X}{\partial \theta_o}\right)_{\text{total}} = -2\rho A_b (\Omega R)^2 (\bar{a}_{1s} + i_m) \left(\frac{\partial C_{T/\sigma}}{\partial \theta_o}\right) \end{aligned}$$

$$\begin{aligned} \left(\frac{\partial X}{\partial B_1}\right)_{\text{right}} &= \left(\frac{\partial X}{\partial B_1}\right)_{\text{left}} \\ &\Rightarrow \left(\frac{\partial X}{\partial B_1}\right)_{\text{total}} = -2\rho A_b (\Omega R)^2 \left(\frac{\partial C_{H/\sigma}}{\partial a_{1s}}\right) \left(\frac{\partial a_{1s}}{\partial B_1}\right) \end{aligned}$$

$$\begin{aligned} \left(\frac{\partial X}{\partial A_1}\right)_{\text{right}} &= -\left(\frac{\partial X}{\partial \theta_o}\right)_{\text{right}} \quad \& \quad \left(\frac{\partial X}{\partial A_1}\right)_{\text{left}} = \left(\frac{\partial X}{\partial \theta_o}\right)_{\text{left}} \\ \left(\frac{\partial X}{\partial A_1}\right)_{\text{right}} &= -\left(\frac{\partial X}{\partial A_1}\right)_{\text{left}} \Rightarrow \left(\frac{\partial X}{\partial A_1}\right)_{\text{total}} = 0 \end{aligned}$$

Table 3.2

b. Y- Force Derivatives

The lateral derivatives are a bit more interesting and challenging. For the same reasons as with the X-force derivatives, many of them turn out to be zero also. However, due to

the significant lateral distance (y_m) between the rotors and the CG, the forces due to yaw perturbations are significant, unlike a conventional helicopter. The yaw perturbation itself has negligible effect, but the forward velocity due to the yaw and the y_m distance is where the effect takes place. This effect would seem to be a negating one, but the counter rotation results in the relation, $\left(\frac{\partial Y}{\partial \dot{x}}\right)_{\text{right}} = -\left(\frac{\partial Y}{\partial \dot{x}}\right)_{\text{left}}$. This causes this effect to be additive as in the $\left(\frac{\partial Y}{\partial r}\right)_{\text{total}}$ derivative shown in Table 3.3. The control derivatives show the same effect, where the lateral inputs are additive and the longitudinal inputs cancel each other.

Y-force Derivatives

Development

Table 3.3 (continued)

c. Z-Force Derivatives

The Z-force derivatives for the longitudinal cases are identical to the helicopter ones in this analysis. They are additive and the equations used in Ref(s). 6 and 7 are applicable by simply multiplying them by two. The lateral derivatives intuitively cancel each other, and the results are shown in Table 3.4.

Table 3.4

2. Moment Derivatives

The moment derivatives have forces embedded in them, along with appropriate moment arms, l_m , y_m , and h_m . The forces of opposite sign here, cause the moments associated with them to be additive. Conversely, the forces of the same sign, have moments that cancel each other. Again, each axis will be presented separately.

a. Roll Moment, R Derivatives

Many of the roll derivatives, including the lateral ones, fall out because of the counter rotation effect. The ones that do not are the roll disturbance and the roll/yaw coupling derivatives. For the roll disturbance derivative, $\frac{\partial R}{\partial p}$, there are two primary effects to consider. First, is the roll effect of each rotor due to a roll disturbance, $\left(\frac{\partial R}{\partial p}\right)_{\text{R or L}} = \frac{\partial R}{\partial b_{1s}} \frac{\partial b_{1s}}{\partial p}$. When the contributions for each rotor are combined, however, this pure roll effect cancels. Second, is the moment induced by the Z-force along with the lateral moment arm, y_m depicted by:

$\left(\frac{\partial Z}{\partial p}\right)_{\text{R or L}} = \left(\frac{\partial Z}{\partial \dot{z}}\right) \left(\frac{\partial \dot{z}}{\partial p}\right)$ and is simplified by knowing that $\left(\frac{\partial \dot{z}}{\partial p}\right)_{\text{(R or L)}}$ is merely equal to y_m (in magnitude). The same analysis was applied to all the other roll moment derivatives and is summarized in Table 3.5.

Table 3.5 (continued)

b. Pitch Moment, M Derivatives

Due to tiltrotor aircraft being symmetric along the longitudinal axis, pitch moments are only generated by longitudinal forces and moments. An example of a pitch moment derivative that is non-zero is the $\frac{\partial M}{\partial \dot{x}}$ derivative. This moment is not effected by the direction of rotation, therefore the left and the right rotor effects will be additive, resulting in the relation shown in Table 3.6, which is simply twice that found in Ref. 6. The lateral perturbations, such as the $\frac{\partial M}{\partial \dot{y}}$ derivative, cancel due to the counter rotation effect leaving all the lateral perturbation derivatives equal to zero. The collective control derivative, $\frac{\partial M}{\partial \theta_o}$ has

contributions from the X-force with the vertical moment arm, y_m and the Z-force coupled with the longitudinal distance, l_m to produce the result also shown in Table 3.6.

Table 3.6 (continued)

c. Yaw Moment, N Derivatives

Yaw moments are, as are the roll moments, lateral mode derivatives. These also result in all the longitudinal disturbances having no contribution to yaw moments. The lateral disturbances cause no pure yaw moments, yet there are significant moments generated by the lateral forces due to the rotor distances from the aircraft cg. These couplings are the X-forces with the y_m distance and the Y-force with the l_m distance. The two yaw moment derivatives due to the lateral rates are somewhat more complicated due to the moments being generated by forces which are themselves generated by the angular rates. This effect was discussed in the roll moment section where the relation, $\left| \left(\frac{\partial \dot{z}}{\partial p} \right)_{(R \text{ or } L)} \right| = y_m$, was used. Using the same analysis, $\left| \left(\frac{\partial \dot{x}}{\partial r} \right)_{(R \text{ or } L)} \right| = y_m$ and both of these relations were used here, to simplify the roll and yaw perturbation derivatives shown in Table 3.7.

The control derivatives are also quite nontrivial. The yaw moment due to a lateral cyclic input, $\frac{\partial N}{\partial A_1}$ has components due to the X-force with the vertical distance, h_m and Y-force with the longitudinal distance, l_m . The yaw moment due to directional pedal input, (by convention) $\frac{\partial N}{\partial \Delta B_1}$ has the same coupling effects as the lateral input, as depicted in the last two derivatives in Table 3.7.

Table 3.7

B. AIRPLANE MODE

As with the helicopter mode, there are some underlying assumptions that need to be made for our simplified model of a tiltrotor flying in airplane mode. The same assumptions from the helicopter section are made with the following additional ones:

1. The wing has constant airfoil section, (i.e., constant a_w)
2. Rotor effects on the airflow over the wing and other parts of the aircraft are negligible.

JANRAD helicopter analysis takes into account airplane type features such as wings, horizontal and vertical stabilizers as discussed in Chapter II. This analysis will use these previously developed relations where they seem to be effective, but some will be modified or re-derived as necessary.

All derivatives are based on a trimmed flight condition and the resulting forces that balance out for each of the three axes. As discussed in the trim section, the forces which are determined by the trim routine are in the wind axis. These forces are lift (L_O) and drag (D_O) and are determined for all the aerodynamic components (the fuselage, wing, horizontal stabilizer and vertical tail). These forces are transformed into the body axis by the relations shown at the beginning of each component sections to follow. Derivatives for each component are then calculated separately and subsequently added to arrive at the total aircraft derivatives.

The flight control derivatives are where Ref. 6 and Ref. 7 fall short for a tiltrotor. Though JANRAD handles many airplane aerodynamic qualities (for the compound helicopter analysis), flight controls are not included because compound helicopters are controlled by normal, helicopter (swashplate) controls. For this reason, the airplane mode flight control derivatives were derived or developed using relations in Ref. 5.

1. Fuselage Derivatives

The first few of the nondimensional derivatives (to be used in the dimensional derivatives later) are taken from Ref. 6 with the rotor downwash effect removed since there is no main rotor above the fuselage affecting the airflow around it. The remaining nondimensional fuselage derivatives of Ref. 6 are determined from performance and aerodynamic charts. This is not practical for an interactive preliminary design tool like JANRAD. These values were

approximated from the charts and "hard wired" into the JANRAD helicopter routine, but are not as useful for the more slender fuselage shape a tiltrotor has. For this reason, these nondimensional fuselage derivatives were taken from XV-15 wind tunnel data [Ref. 2].

The dimensional derivatives of Ref. 6 were adequate for this analysis, therefore they were used with no modifications and are given in Table 3.8.

$$\left(\frac{\partial M}{\partial \dot{z}} \right)_F = q \frac{\partial (M/q)}{\partial \alpha_F} \frac{\partial \alpha_F}{\partial \dot{z}}$$

$$\left(\frac{\partial N}{\partial \dot{y}} \right)_F = q \frac{\partial (N/q)}{\partial \beta} \frac{\partial \beta}{\partial \dot{y}}$$

Table 3.8 (continued)

2. Wing Derivatives

The dominant aerodynamic component to be included in the derivatives (for a tiltrotor in airplane mode) is the wing. The wing is the primary Z-force contributor and is a major X-force contributor in cruise. There is a need for a more detailed analysis with the helicopter

relations given in Ref. 6. Ref. 6 did not give any wing derivatives, however, Ref. 7 took the relations given in Ref. 6 for a Horizontal tail section and modified them for a wing. This works fine since they are basically both simple airfoils. The JANRAD helicopter derivatives were used with the main rotor influence terms removed. The only relations that were added for a tiltrotor were the control derivatives. These relationships were taken from Ref. 5 and/or derived using standard aerodynamic relationships. The resulting wing derivatives are depicted in Table 3.9.

Wing Equations and Derivatives

Force and Moment (Trim)

$$L_w = qA_w a_w (\theta + i_w - \epsilon_{FW} - \gamma_c - \alpha_{ol}) \quad \Rightarrow \quad C_{Lw} = L_w / (qA_w)$$

$$\left(\frac{\partial N}{\partial \delta_a}\right)_w = \frac{q A_w (1 + \delta_{iw})}{2 \pi A R} \frac{\partial C_{lw}}{\partial \delta_a}$$

Table 3.9 (continued)

3. Horizontal Tail

The horizontal tail, (H-stab) for analysis purposes, is nothing more than another wing further aft from the center of gravity. For this reason, there are only a few subtle differences in the derivatives from the wing derivatives. First, JANRAD allowed for the difference in dynamic

pressure between the wing and the tail with the parameter, q_H/q . This parameter will remain in the tiltrotor analysis. Second, most airplane designs have symmetrical H-stabs which have zero lift at zero angle of attack. Allowing $\alpha_{ol(H)} = 0$, here, simplifies the wing equations somewhat, resulting in the ones shown in Table 3.10. The final differences from the wing derivatives apply the fact that the H-stab span, b_H is much shorter than the wing's, so the lateral derivatives for the R and N moments are small. Compared to the wing derivatives, these are essentially zero and are therefore excluded.

Horizontal Tail Equations and Derivatives

Force and Moment (Trim)

$$L_H = \left(\frac{q_H}{q} \right) q A_H a_H \overbrace{(\theta + i_H - \varepsilon_{FH} - \gamma_c)}^{\alpha_H} \quad \Rightarrow \quad C_{L_H} = \frac{L_H}{q_H A_H}$$

$$D_H = \left(\frac{q_H}{q} \right) q A_H \left[\frac{C_{L_H}^2 (1 + \delta_{i_H})}{\pi A R} + C_{D_{oH}} \right]$$

$$X_H = -D_H \cos(\theta - \varepsilon_{FH} - \gamma_c) + L_H \sin(\theta - \varepsilon_{FH} - \gamma_c)$$

$$Z_H = -L_H \cos(\theta - \varepsilon_{FH} - \gamma_c) - D_H \sin(\theta - \varepsilon_{FH} - \gamma_c)$$

Nondimensional Derivatives

Table 3.10 (continued)

4. Vertical Tail

The final set of derivatives to be developed are also not that different from the previous sections. A vertical tail is also not much different from a wing positioned vertically. For an airplane, they usually have a full span rudder causing a change in the side force (side lift) in the same manner a flap or aileron change the lift on a wing. A twin vertical tail has the same effect as a single tail with twice the reference area, A_v , when interference and prop rotor effects are neglected, therefore there is no need to complicate the analysis with trying to deal with multiple vertical tails. The addition of a control surface (rudder) is the only real difference in these relations, shown in Table 3.11 have from Ref. 6.

Vertical Tail Equations and Derivatives

Force (Trim)

$$L_v = \left(\frac{q_v}{q} \right) q A_v a_v(\beta) \approx 0 \quad \Rightarrow \quad C_{L_v} \approx 0$$

$$D_v = \left(\frac{q_v}{q} \right) q A_v \left[\frac{C_{L_v}^2 (1 + \delta_{iv})}{\pi A R_v} + C_{D_{ov}} \right] = \left(\frac{q_v}{q} \right) q A_v C_{D_{ov}}$$

$$X_v = -D_v \cos(\theta - \epsilon_{FH} - \gamma_c)$$

Table 3.11 (continued)

IV. MODEL VERIFICATION

A. METHODOLOGY

Model verification is based on comparing JANRAD output for the stability derivatives and other data generated with data obtained from industry models of the XV-15 and the V-22. There are essentially four ways (feasible in this thesis) to verify or compare the JANRAD model with the tested models; these involve comparing the following stability analysis tools:

1. The stability and control derivatives themselves.
2. The roots of the plant (A) matrix.
3. Frequency response or Bode plots.
4. Time response to various inputs.

Because of the lack of availability of some detailed V-22 information, #2 is the only comparison feasible with the V-22. Comparisons 1, 3 and 4 are made with only the XV-15 model. The two tested models used for comparison come from two separate sources and they both have to be converted to the JANRAD format before they can be analyzed. The details about the source of the data and the data conversion process for each model are discussed in the following two sections.

1. XV-15 Tiltrotor Model Data Conversion

The mathematical model for a Generic Tilt-Rotor System (GTRS) was developed by Bell Helicopter Textron (BHT) under a NASA contract. As discussed in Ref. 2, this model was made for real time simulation use on a VAX computer in support of aircraft design, pilot training and flight testing. The model was verified by applying XV-15 unique physical and aerodynamic characteristics and comparing the dynamics to XV-15 flight test data [Ref. 3] for trim conditions similar to those investigated by this thesis. Reference 2 is the mathematical model with the equations of motion and many aerodynamic relationships used in the GTRS model. This reference was used extensively in the development of the stability derivatives used in this research, along with detailing logical sign conventions that make the analysis of tiltrotor dynamics easier.

The primary source of information for our analysis is Ref. 4. Reference 4 is the result of the generic tiltrotor model run for two cases, an out of ground effect hover, and a 200 knot cruise

at a low altitude with the nacelles and rotor system in the airplane mode. The first set of information taken from Ref. 4 is the aircraft configuration and flight conditions. In order to perform an accurate comparison of the models, all these parameters should be as close as possible to each other. Most of these parameters were entered using JANRAD's input routine and saved as the Matlab data file, XV15H.MAT for the helicopter flight condition and XV15A.MAT for the cruise (airplane) conditions. All the conditions are depicted in Ref. 4 found in Appendix K.

All the trim parameters are also listed in Ref. 4 which for the helicopter mode proved to be very important. When the XV-15 hover configuration and flight conditions were applied to the JANRAD trim section, the trim parameters were not satisfactorily close to those in Ref. 4. Since the helicopter trim routine was not written by this project, its accuracy for a tiltrotor is questionable. Therefore, the hover model generated by this project was generated without the use of the JANRAD trim routine. The trim parameters were inserted (with a data file) to ensure both models had the same trim reference point. The airplane mode trimming routine written by this project did not have the same problem as the helicopter mode trim. Reference 4 airplane trim parameters matched fairly close to the results of the airplane trimming routine..

Once the trimming parameters were consistent, the resulting stability derivatives were compared. The model put through their verification process is based on a set of seven force and moment equations of motion, with the rotor rpm being the seventh state and rotor torque being the seventh (moment) equation. A helicopter is normally considered a constant rpm and (for a trim condition) constant torque machine. For small perturbation simulation modeling however, rotor rpm is a state that does have perturbations that effect the states in our state space and should not be considered constant. However, to remain consistent with JANRAD's structure, rotor rpm was not included in our state space. Our verification will be to compare our six degree of freedom model to theirs with the seventh (rotor rpm) removed. This is essentially the same as assuming the rotor rpm and torque to be constant, which is the assumption made in both Refs. 6 and 7.

Stability derivatives are generated in the GTRS model software using a small perturbation numerical routine described in Reference 4. The derivatives are not used in the simulation process but are calculated for analysis only. Derivatives are generated in both the body and rotor axes as depicted in Appendix K, but only body axis derivatives are used for comparison. To be compared directly, a separate routine was written to generate them because

JANRAD does not output the derivatives themselves. The GTRS generated stability and control derivatives for both modes were extracted from Ref. 4 and are compared with those found with JANRAD. The listing of all the stability and control derivatives is found in section B with Tables 4.1 and 4.2, respectively, for the hover mode and Tables 4.3 and 4.4 for airplane mode.

JANRAD displays the [A] and [B] matrices formed with derivatives and the appropriate moments of inertia, aircraft mass, etc. of the format shown in Appendix B [Ref. 8]. The GTRS generated stability derivatives shown as "Total" in the tables for both modes were extracted from Ref. 4 and also inserted into the same matrix of App. B to produce the A and B matrices for each flight regime. The matrices themselves could be compared directly but that would not be any more enlightening than comparing the stability and control derivatives. The matrices generated by JANRAD can be found in Appendices C and D, along with the JANRAD input and generated data.

2. V-22 Osprey State Space Model Conversion

The V-22 data availability limits the degree of comparison that can be made for this project. The preferred method of comparison would be to attain the same physical characteristics that was used in developing the XV-15 model and use JANRAD to construct a model for the V-22. However, this information such as the aerodynamic relationships, component and center of gravity locations was not available.

The information that was available was an airframe state space model of the V-22. This model is one of many modules used to simulate the entire V-22 aircraft for the V-22 Manned Flight Simulator (MFS) at the Navy's Flight Test Center in Patuxent River, Maryland. The module applicable here is the airframe/rotor dynamics module, which contains not only the nine states in our model but also altitude and the longitudinal and lateral flapping angles for each rotor. The module contains all four matrices (A, B, C, and D of the classical form), however the A matrix is all that will be used in our comparison. Because this model is only one of many modules that represent all aspects of the V-22, the B matrix of the MFS model contains configurations that do not allow easy conversion to the JANRAD control input format of the four normal aircraft controls. Therefore, only the A matrix of this module is used, which corresponds to the state vector:

$$\mathbf{x}_{af/rotor} = [u, v, w, p, q, r, \Phi, \theta, \Psi, alt, a_{1s(L)}, a_{1s(R)}, b_{1s(L)}, a_{1s(R)}] \quad (4.1)$$

This state vector can be transformed to the JANRAD state vector format by eliminating the last five states, resulting in the state vector,

$$\mathbf{x}'_{af/rotor} = [u, v, w, p, q, r, \Phi, \theta, \Psi], \quad (4.2)$$

and then using a transformation matrix, \mathbf{T} , where $\mathbf{x}_{JANRAD} = \mathbf{T} \mathbf{x}'_{af/rotor}$. Eliminating the final five states is, again, essentially the same as assuming them to be constant, which is how JANRAD treats these parameters. Reducing the order of the A matrix by the same amount does not change the equations. The transformation matrix \mathbf{T} was used to transform the A matrix into the JANRAD formatted matrix, \mathbf{A}' as follows:

$$\dot{\mathbf{x}}_{af/rotor} = [\mathbf{A}_{af/rotor}] \mathbf{x}_{af/rotor} + [\mathbf{B}_{af/rotor}] \mathbf{u} \quad (4.3)$$

$$\dot{\mathbf{x}}'_{af/rotor} = [\mathbf{A}'_{af/rotor}] \mathbf{x}'_{af/rotor} + [\mathbf{B}_{af/rotor}] \mathbf{u} \quad (4.4)$$

$$\mathbf{T}^{-1} \dot{\mathbf{x}}_{JANRAD} = [\mathbf{A}'_{af/rotor}] \mathbf{T}^{-1} \mathbf{x}_{JANRAD} + [\mathbf{B}_{af/rotor}] \mathbf{u} \quad (4.5)$$

$$\dot{\mathbf{x}}_{JANRAD} = \mathbf{T} [\mathbf{A}'_{af/rotor}] \mathbf{T}^{-1} \mathbf{x}_{JANRAD} + \mathbf{T} [\mathbf{B}_{af/rotor}] \mathbf{u} \quad (4.6)$$

$$\dot{\mathbf{x}}_{JANRAD} = [\mathbf{A}'] \mathbf{x}_{JANRAD} + \mathbf{T} [\mathbf{B}_{af/rotor}] \mathbf{u} \quad (4.7)$$

This results in the transformation, $\mathbf{A}' = \mathbf{T} [\mathbf{A}'_{af/rotor}] \mathbf{T}^{-1}$. The transformed \mathbf{A}' matrix is the source of comparison to the other models. The actual matrices that went through these transformations along with the resulting matrix are found in Appendix F. The control matrix is not included here because the control rigging relationships, as well as the control derivatives, were not available. The natural frequencies and the matrix itself are, therefore, the only real set of figures that can be used for comparison with the other models.

B. DISCUSSION OF MODEL COMPARISON

1. Stability Derivatives

XV-15 stability derivative information of Ref. 4 is conveniently divided into their two major contributors, rotor and airframe. The derivatives used in the GTRS model are the sum of

the two, giving the "Total" aircraft derivatives. The JANRAD hover mode model assumes the airframe effect to be negligible and, therefore, no airframe effect is included in the JANRAD model. Table 4.1 shows the breakdown of the GTRS derivatives in order to see how good JANRAD's assumption is.

Derivative	JANRAD	GTRS (XV-15) Model		
		Total	Rotor	Airframe
X_q	528.7	531.51	531.91	-0.4
X_u	-5.01	-5.13	-4.64	-0.49
X_w	-1.03	-1.09	-1.13	0.04
Y_p	-559.8	-506.58	-506.41	-0.17
Y_r	-9.38	-156.39	-159.08	2.69
Y_v	-5.01	-23.02	-5.92	-17.11
Z_q	0	108.14	129.6	-21.45
Z_u	0	-28.57	-29.4	0.83
Z_w	-77.16	-80.17	-77.42	-2.75
L_p	-23,430.04	-19,022.5	-24,515.78	5,493.28
L_r	58.09	6,152.93	6,632.97	-480.04
L_v	-49.72	-265.93	-237.54	-28.39
M_q	-5,134	-4,286.12	-4,232.63	-53.48
M_u	49.72	15.33	6.86	8.46
M_w	5.72	-0.46	6.81	-7.27
N_p	2,071	10,464.46	10,460.51	3.95
N_r	-1,294	-2,037.07	-1,974.26	-62.81
N_v	9.42	85.83	82.53	3.31

Table 4.1 Comparison of Hover Mode Stability Derivatives

As it can be seen from the GTRS hover model in Table 4.1, ten of the sixteen derivatives have negligible airframe effects where the lateral derivatives, L_p and Y_v , account for the most noticeable airframe effects. The Y_v effect can be explained by the fact that the airframe has more drag from a sideward wind than the rotor system has. All the airframe effects are basically due to the change in the airflow around the airframe due to small perturbations in the relative wind. This comparison leads to the conclusion that neglecting the airframe effects may not be a good assumption.

The more important comparison here is how the "Rotor" derivatives compare with those of JANRAD's. This analysis will determine how effective JANRAD's stability derivative equations are. With this analysis, only half of the hover model derivatives compare well, with the Z derivatives and L_r are the least comparable of the sixteen derivatives.

With the control derivatives shown in Table 4.2, neglecting the airframe effect in a hover proves to be a valid assumption for all but one derivative, $M_{\delta c}$. The pitching moment effect for the collective input is significant and clearly cannot be neglected. As far as comparing the control derivatives between models, they do not seem very comparable. With exception of the collective control to pitch derivative, they are all the correct sign and are of the same order of magnitude. Another observation is that the primary control derivatives (the derivatives of the intended response such as $X_{\delta e}$, $Y_{\delta a}$, $Z_{\delta c}$, $L_{\delta a}$, $M_{\delta e}$, and $N_{\delta p}$) are the more accurate and dominate in magnitude over the cross control derivatives. This may prove to make the overall model more accurate than it appears from these values.

Derivative	JANRAD	GTRS (XV-15) Model		
		Total	Rotor	Airframe
$X_{\delta e}$	253.1	537.46	537.46	0
$X_{\delta c}$	-28.75	-34.07	-34.07	0
$Y_{\delta a}$	-2.53	-17.53	-17.53	0
$Y_{\delta p}$	0	98.82	98.82	0
$Z_{\delta e}$	0	6.23	7.18	-0.95
$Z_{\delta c}$	-2,162	-2,164.63	-2,432.23	267.6
$L_{\delta a}$	13,850	12,753.15	13,526.8	-773.65
$L_{\delta p}$	0	1,099.79	1,093.81	5.98
$M_{\delta e}$	-2,513	-4,030.16	-4,030.76	0.61
$M_{\delta c}$	160.2	-60.89	104.62	-165.51
$N_{\delta a}$	-180.6	-1,694.22	-1,694.23	0.01
$N_{\delta p}$	3,102	6,643.45	6,643.45	0

Table 4.2 Comparison of Hover Mode Control Derivatives

The airplane model has problems similar to those of the helicopter model. Table 4.3 shows the comparison between JANRAD stability derivatives and the GTRS generated ones. Because the airplane mode stability derivatives are based solely on the airframe effects, the

GTRS airframe contribution is listed next to the total derivatives in the table. From this table, it is clear that assuming the rotor derivatives to be negligible in the airplane mode is not an accurate assumption. In eleven of the sixteen stability derivatives, the rotor contribution is clearly not negligible, and in 6 of these, the rotor contribution dominates the derivative. As far as a check of the JANRAD derivative equations, the table shows a good comparison between the JANRAD derivatives and the GTRS airframe derivatives.

Derivative	JANRAD	GTRS (XV-15) Model		
		Total	Airframe	Rotor
X_q	0	381.65	-9.13	390.78
X_u	-6.91	-167.22	-13.18	-154.04
X_w	23.48	29.44	28.04	1.4
Y_p	-257.7	-467.62	-384.02	-83.6
Y_r	1,629	3,684.5	1,474.79	2,209.72
Y_v	-105.4	-151.31	-119.34	-31.97
Z_q	-1,192	-4,983.29	-2,765.34	-2,217.95
Z_u	-77.13	-69.05	-64.89	-4.16
Z_w	-522.6	-487.88	-456.28	-31.6
L_p	-32,980	-41,002.57	-27,197.33	-13,805.24
L_r	11,090	-2,239.51	9,832.69	-12,072.2
L_v	-430.2	-676.91	-594.38	-82.53
M_q	-26,190	-44,624.14	-52,201.97	7,577.83
M_u	64.27	438.22	68.38	369.84
M_w	-794.9	-758.47	-913.43	154.96
N_p	4,223	-11,752.99	5,575.94	-17,328.92
N_r	-37,520	-67,257.17	-35,061.92	-32,195.25
N_v	1,164	655.53	870.31	-214.78

Table 4.3 Comparison of Airplane Mode Stability Derivatives

As expected, the control derivatives compared more favorably than the stability derivatives. Table 4.4 demonstrates that the rotor does play a negligible role in all the airframe control derivatives (δ_e , δ_a , and δ_p) and the expected dominate role in the power control (δ_c) derivatives. The one exception is the flaperon to yaw derivative, N_{δ_a} which shows an unexpected rotor influence to be dominant with the lateral input.

Derivative	JANRAD	GTRS (XV-15) Model		
		Total	Airframe	Rotor
$X_{\delta e}$	0	-26.52	-26.52	0
$X_{\delta c}$	2,020	2,064.32	43.67	2,020.65
$Y_{\delta a}$	0	1.67	0	1.67
$Y_{\delta p}$	-931.4	-1,095.47	-1,095.47	0
$Z_{\delta e}$	-1,159	-1,284.67	-1,284.67	0
$Z_{\delta c}$	0	24.87	-34.01	58.88
$L_{\delta a}$	18,620	16,946.88	15,614.62	1,332.25
$L_{\delta p}$	-3,360	-3,950.05	-3,950.05	0
$M_{\delta e}$	-25,470	-29,169.63	-29,169.63	0
$M_{\delta c}$	-3,948	-4,967.37	-94.48	-4,872.89
$N_{\delta a}$	-282.6	5,694.52	1,721.01	3,973.52
$N_{\delta p}$	21,240	25,679.72	25,679.72	0

Table 4.4 Comparison of Airplane Mode Control Derivatives

2. Plant Eigenvalues

The next model comparison to be made is analyzing the natural frequencies of both models. The uncoupled plants for the hover mode will be compared first, followed by the uncoupled plants of the airplane mode. All three model plants will be compared together for each of the two modes.

a. Hover Mode

The root analysis of both (longitudinal and lateral) models highlights that both JANRAD and GTRS models have similar root distributions. The V-22 roots, used as a sanity check, shows the same distribution. The longitudinal model root distribution is shown in Figure 4.1. It shows the oscillatory mode (similar to the airplane phugoid) being comparable in both frequency and damping. As for the non-oscillatory roots, the short period roots are not as close as the long period but they are both comparable.

JANRAD (XV-15) Longitudinal (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.1360 + 0.3522i$	-0.3602	0.3775
$0.1360 - 0.3522i$	-0.3602	0.3775
-0.5244	1.0000	0.5244
-0.1913	1.0000	0.1913

Compared with the GTRS (XV-15) Longitudinal (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.0810 + 0.2352i$	-0.3256	0.2487
$0.0810 - 0.2352i$	-0.3256	0.2487
-0.3733	1.0000	0.3733
-0.2005	1.0000	0.2005

Figure 4.1 Comparison of Longitudinal (Hover) Models

And the MFS (V-22) Longitudinal (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.1933 + 0.4004i$	-0.4349	0.4446
$0.1933 - 0.4004i$	-0.4349	0.4446
-0.1416	1.0000	0.1416
-0.5065	1.0000	0.5065

The lateral roots depicted in Figure 4.2 are not as comparable as the longitudinal ones but do have comparable root distributions. The JANRAD oscillatory roots are within 50% of GTRS's frequency and damping. The real roots of the JANRAD model are closer to each other on the real axis than those of the GTRS model. These less comparable results are consistent with the stability derivative analysis of Section 1.

JANRAD Lateral (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.0467 + 0.2302i$	-0.1986	0.2349
$0.0467 - 0.2302i$	-0.1986	0.2349
-0.5485	1.0000	0.5485
-0.0199	1.0000	0.0199
0	-1.0000	0

Compared with the GTRS (XV-15) Lateral (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.1445 + 0.4459i$	-0.3083	0.4688
$0.1445 - 0.4459i$	-0.3083	0.4688
-0.7305	1.0000	0.7305
-0.0008	1.0000	0.0008
0	-1.0000	0

Figure 4.2 Comparison of Lateral (Hover) Models

And the V-22 Lateral (Hover) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$0.3014 + 0.6583i$	-0.4163	0.7241
$0.3014 - 0.6583i$	-0.4163	0.7241
-0.8587	1.0000	0.8587
-0.0918	1.0000	0.0918
0	-1.0000	0

b. Airplane Mode

The models of the airplane mode have the roots shown in Figures 4.3 and 4.4.

Again, the root analysis initially looks promising due to their distribution being so similar to each other. The longitudinal roots have similar shapes in that all three models each have two sets of oscillatory roots. The two XV-15 models compare very well with the frequencies of both (phugoid and short period) modes being within 5% of each other and the damping being very comparable as well.

JANRAD (XV-15) Longitudinal (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
$-1.2941 + 3.5888i$	0.3392	3.8150
$-1.2941 - 3.5888i$	0.3392	3.8150
$-0.1951 + 0.1703i$	0.7533	0.2590
$-0.1951 - 0.1703i$	0.7533	0.2590

Figure 4.3 Comparison of Longitudinal (Airplane) Models

Compared with the GTRS (XV-15) Longitudinal (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
-1.6948 + 3.4555i	0.4403	3.8488
-1.6948 - 3.4555i	0.4403	3.8488
-0.2115 + 0.1576i	0.8018	0.2637
-0.2115 - 0.1576i	0.8018	0.2637

And the MFS (V-22) Longitudinal (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
-0.1002 + 0.2719i	0.3457	0.2898
-0.1002 - 0.2719i	0.3457	0.2898
-1.3340 + 0.9354i	0.8188	1.6293
-1.3340 - 0.9354i	0.8188	1.6293

The lateral roots again, do not fare as well as the longitudinal ones. As seen in the root listing, the models do compare with having the same number of oscillatory and pure real roots but the frequencies and damping could be closer. The JANRAD oscillatory roots (probably be Dutch roll) have a natural frequency 30% greater than that of the GTRS model and 60% the damping. The real roots do not compare favorably either with the JANRAD roots having significantly longer periods than the GTRS model.

JANRAD Lateral (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
-0.3958 + 2.3767i	0.1643	2.4094
-0.3958 - 2.3767i	0.1643	2.4094
-0.6645	1.0000	0.6645
-0.0058	1.0000	0.0058
0	-1.0000	0

Compared with the GTRS (XV-15) Lateral (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
-0.4989 + 1.7702i	0.2712	1.8392
-0.4989 - 1.7702i	0.2712	1.8392
-1.0649	1.0000	1.0649
-0.1226	1.0000	0.1226
0	-1.0000	0

And the V-22 Lateral (Airplane) Model Roots:

Eigenvalue	Damping	Freq. (rad/sec)
-0.1212 + 0.8156i	0.1470	0.8245
-0.1212 - 0.8156i	0.1470	0.8245
-1.0526	1.0000	1.0526
-0.1354	1.0000	0.1354
0	-1.0000	0

Figure 4.4 Comparison of Lateral Airplane Models (Roots)

3. Frequency Responses

A graphical comparison of the frequency domain analysis is the Bode plots. The old JANRAD produced Bode plots for all the applicable control inputs as one of its output routines. This routine was used to produce frequency responses for all states for each of the four inputs and are depicted listed in Appendix G for both hover and airplane models. The same plots were generated for the GTRS model and all the plots can be found in Appendix H. For the best comparison, the plots generated would preferably be done on the same set of axes or have the same scale, but with the number of plots generated, the given JANRAD plotting routines were used which produce the scale as shown. The appropriate input to desired output responses of the JANRAD model are compared to those of the GTRS model in the following subsections.

a. Hover Mode

The longitudinal plants compare very well as seen in Figures 4.5 and 4.6. Though the shapes of the two longitudinal cyclic responses are very close, the JANRAD model peaks at -12 dB where the GTRS model peaks at -4 dB. This 8 dB difference equates to a factor of about 6 meaning the GTRS model would respond six times more than the JANRAD model

Figure 4.5 Comparison of Longitudinal Cyclic Frequency Responses, Hover

with an input of the same frequency (~ 0.3 rad/sec). The collective input responses are expectedly very close since the thrust derivatives and the masses of the two models are the same.

Figure 4.6 Comparison of Collective Frequency Responses, Hover

The lateral model responses of Figure 4.7 show slightly different shapes however, the major difference is in the trough seen in the low frequency range of the JANRAD response. This anomaly may be insignificant, however, due to how low the frequency is. The peak response is where the significant difference may show up. Here, the JANRAD response shows about a 8 dB higher peak response at a 2.5 rad/sec lower frequency. This indicates that the JANRAD hover model is more responsive to lateral inputs than the GTRS model.

Figure 4.7 Comparison of Lateral Cyclic Frequency Responses, Hover

The directional pedal response comparison of Figure 4.8 shows nothing more than a frequency shift. This corresponds to a shift in magnitude as well since the frequency responses are linear (in dB) for most of the frequency range. The JANRAD model here, has a 7 dB lower response than the GTRS model.

Figure 4.8 Comparison of Directional Pedals Frequency Responses, Hover

b. Airplane Mode

The airplane models performed somewhat better than the hover models. Figures 4.9 and 4.10 shows the comparison of the longitudinal cyclic and collective input responses respectively with very favorable results. In both comparisons, the frequency responses are almost indistinguishable.

Figure 4.9 Comparison of Longitudinal Cyclic Frequency Responses, Airplane

Figure 4.10 Comparison of Collective Frequency Responses, Airplane

The lateral frequency response comparisons shown in Figures 4.11 and 4.12 look favorable. The JANRAD lateral cyclic response shows a peak response of 3 dB more than the GTRS peak response at the lower break frequency but having virtually the same magnitude

Figure 4.11 Comparison of Lateral Cyclic Frequency Responses, Airplane

for the frequencies above about 5 rad/sec. The pedal input responses have the same shape except for the lower frequencies. With close inspection of the peaks and troughs however, the comparison shows the magnitudes to be very close as well as the frequencies in which they occur.

Figure 4.12 Comparison of Directional Pedals Frequency Responses, Airplane

4. Time Responses

The models that JANRAD produce are merely trimmed condition ones which are not "true" dynamic models. Therefore, any type of time response using the MATLAB Control Systems Toolbox functions would not really depict any "true" dynamic response because very quickly after a disturbance, the trimmed condition has changed to where the model (plant) would no longer be valid. The time response output routine was added to JANRAD so that the initial response of a control input could be used for comparison and comparison only. As with the command bandwidth plots, time response plots were generated for all inputs and outputs for both the JANRAD models and the GTRS models and they can be found in Appendices I and J respectively. For all the inputs to their respective desired outputs, the time responses are shown and discussed in the following subsections.

a. Hover Mode

The longitudinal models compare very well as seen in the time responses of Figures 4.13 and 4.14. The longitudinal cyclic response shows the JANRAD model to be less

Figure 4.13 Comparison of Time Responses to Long. Cyclic Input , Hover

responsive with a -0.055 rad/sec (-3.15 deg/sec) max pitch rate when a 0.5 sec cyclic pulse was applied versus the -.09 rad/sec (5.16 deg/sec) pitch rate the GTRS model showed. The collective to vertical rate response in Figure 4.14 compared so well probably because the it is mostly due to the $\frac{\partial C_T/\sigma}{\partial \theta_0}$ derivative being the same between the models. This thrust derivative (which essentially determines the change in thrust with a change in collective pitch) was taken directly

Figure 4.14 Comparison of Time Responses to Collective Input, Hover

from the XV-15 GTRS reference and "hardwired" in the code, therefore the time responses should be the same since the mass of the two aircraft models are the same.

The lateral models depicted in Figures 4.15 and 4.16 were not as comparable as the longitudinal ones. The max roll rate achieved for a lateral cyclic input were about the same at ~ 0.12 rad/sec (6.8 deg/sec), but the JANRAD model has a noticeable lower frequency

Figure 4.15 Comparison of Time Responses to Lateral Cyclic Input, Hover

response to the GTRS model. The pedal doublet response shows that the JANRAD model has about 50% the response to a pedal input the GTRS model has. These observations are consistent with the frequency response seen in Appendices G and H and discussed in the previous section.

Figure 4.16 Comparison of Time Responses to Directional Pedal Input, Hover

a. Airplane Mode

The airplane mode longitudinal responses depicted in Figures 4.17 and 4.18 show very close matches between the models. This may conclude the concerns about the inconsistencies with the stability derivatives as well as the eigenvalues may not play as great a role as previously discussed. Both longitudinal and power input responses are almost indistinguishable between the JANRAD and GTRS plants.

Figure 4.17 Comparison of Time Responses to Longitudinal Cyclic Input, Airplane

Figure 4.18 Comparison of Time Responses to Collective Input, Airplane

As seen with the frequency responses, the time response to a lateral stick input compared fairly well for the airplane model. Figure 4.19 shows the GTRS roll rate response

Figure 4.19 Comparison of Time Responses to Lateral Cyclic Input, Airplane

comparing very closely to that of the JANRAD's. The peak response is within 10 % and the only distinguishable difference is that JANRAD seems to be slightly overdamped where the GTRS model is slightly underdamped. Figure 4.20 shows the two models comparing very well in magnitude and damping when responding to the same pedal input.

Figure 4.20 Comparison of Time Responses to Directional Pedal Input, Airplane

V. CONCLUSIONS AND RECOMMENDATIONS

A. CONCLUSIONS

JANRAD has been verified to be a good preliminary design tool for helicopter performance analysis. The purpose of this thesis has been to evaluate the program for stability and control. JANRAD is an extensive program covering many areas of rotorcraft preliminary design to include performance, blade dynamics, and stability and control. The six degree of freedom state space model in JANRAD is unquestionably much simpler than the higher order models used to compare its results. However, its simplicity is one of its redeeming qualities. This project has attempted to verify its own modifications, and the results are fairly good. JANRAD was not originally written as a tiltrotor program. Therefore, it is not surprising that for this different type of aircraft, initial comparisons using helicopter-based stability and control derivatives did not look promising. The discrepancies involved the Prouty (Ref. 6) equations JANRAD uses and the assumptions about the fuselage effects in the hover mode and rotor effects in the airplane mode. These discrepancies point to the need for continued improvements in the modeling process.

The analysis of the root locations provided a clearer picture on the accuracy of the JANRAD generated model. This analysis demonstrated that both hover and airplane models were reasonably good when comparable modes in both uncoupled (longitudinal and lateral) plants were compared. Including the MFS model in the comparison proved valuable in verifying the plant/model conversion process to the JANRAD form. It also served as a good "sanity check" in that another tiltrotor (V-22) aircraft has the same basic modes as the JANRAD and GTRS XV-15 plants.

The other frequency domain analysis tool, Bode magnitude plots, provided the most information. In general, Bode plots compared well between the models. The longitudinal plants of both modes compared much better than the lateral plants. The frequency responses of the lateral modes show that the modeling equations should be improved. It was concluded that the lateral stability and control derivatives are the most likely source of the discrepancies encountered.

The final analysis tool used was a comparison of time histories. These comparisons showed promising results. Responses were similar if not indistinguishable in many of the comparisons. Any significant differences that occurred were in magnitude only. In some

comparisons there were slightly more or less damping, but in general, responses were comparable. Overall, the new tiltrotor routines) provide a fairly accurate assessment of the stability and control aspects of a tiltrotor in the preliminary stage of design.

B. RECOMMENDATIONS

The first set of recommendations is to complete the goal of having a truly usable tiltrotor stability and control routine in JANRAD. This project accomplished most of this goal. The following are additional tasks needed to complete the work.

1. Develop a tiltrotor performance section to:
 - a. Incorporate and validate C_T/σ , etc. derivatives
 - b. Develop a common trim routine for both tiltrotors and helicopters in all flight regimes.
2. Add a program to input many "hardwired" data found in various routines
3. Modify (long) stick movement to be consistent with helicopter section (aft=pos)

The JANRAD performance section has been verified with data obtained on an H-60 helicopter (Eccles, Ref. 9). Eccles showed excellent agreement but the helicopter methods did not work well with trimming a tiltrotor aircraft. The existing routine is used by the stability and control trim routine to provide trim swashplate positions for the main rotor and the tail rotor. This routine is also used iteratively to get derivatives such as C_T/σ needed in the stability and control section. This project used constant data found or calculated with data in Ref. 4. Existing performance routines) should be modified and then verified versus XV-15 or V-22 data to provide baseline performance data for tiltrotor aircraft.

The trim routine attempted to be used in this project, TILTTRIM.M, was one that was a modification of the previous routine, TRIM.M. Although this project did not use the TILTTRIM.M results, it does work for both helicopter and tiltrotor trimming. The routine was originally written for use in a tiltrotor design, but it was not written for general purpose. Modifications could be incorporated to make it fully functional in the JANRAD program for both types of rotorcraft.

Another set of modifications to make a truly functional stability and control section would be to incorporate a list of input parameters that would eliminate the "hardwired" data in the JANRAD routine. CBODYGRP.M, CTRGRP.M, and CTLTRGRP.M all have data such as

this in their first few lines of code that are not calculated or input. Most of these derivatives or constants are in these routines because they were taken from a plot, and an equation for them was not easily obtained. The problem is that they are only accurate for a particular type and size of aircraft and need to be modified for each design. These items could be incorporated using scaling factors that could be part of the input set of data or could even be calculated using the fuselage length or rotor radius depending upon the type of derivative in question.

The next set of recommendations are for improving on the accuracy of the tiltrotor modeling process. The stability and control derivative comparisons produced unfavorable results that could be improved. One improvement would be to include the airframe effects on the hover mode dynamics. This could be done by developing derivatives for the more influential airframe hover stability derivatives such as Y_v , L_p , M_u , and M_w and control derivatives such as $L_{\delta a}$ and $M_{\delta c}$. Another improvement would be to include the rotor influence in the airplane mode. This would be done by developing relationships for some of the more influential (in the airplane mode) rotor stability derivatives, such as X_q , X_u , Y_r , Z_q , L_p , L_r , M_u , N_p , and N_r , and the influential control derivatives such as $N_{\delta a}$. The incorporation of these derivatives would undoubtedly improve the accuracy of the JANRAD models.

One bit of design criterion that is used in both flying tiltrotor aircraft is the wing's dihedral and sweep. Both designs have positive dihedral for stability purposes and forward sweep that also affects their stability characteristics. These angles are easily accessible and also could be incorporated in the airframe stability derivatives if the proper relationship is used.

Another recommendation for further research related to the JANRAD program is to verify its results for an existing helicopter. Stability and control derivatives and entire plants for virtually all flight conditions are available for the H-60 as part of the NASA H-60 program. Similar to this project, parameters acquired from that program could be input using JANRAD, and the subsequent models/plants could be compared to the NASA results. This would be a method of validating the JANRAD stability and control section for a helicopter.

JANRAD is an effective tool for preliminary design, but it is not perfect and could always be improved. Its greatest attribute, however, is that it is easily updated and can be modified for future design needs.

APPENDIX A. JANRAD INPUT PARAMETERS LIST

JANRAD Input Parameters

Basic JANRAD

PA = Pressure altitude (ft)
temp = Temperature (deg F)
Vinf = Airspeed (knots): ')*1.68894444;
GW = Aircraft gross weight (lbs)
b = Number of blades
R = Blade radius: center of hub to blade tip (ft)
rchord = Blade root chord (ft)
e = Hinge offset (ft)
grip = Non-aerodynamic inboard portion of blade (ft)
twist = Blade twist (deg): ')/57.3; ,twist=abs(twist);
wblade = Weight of aero portion of one blade (lbs)
nbe = Number of blade elements
omega = Rotor rotational velocity (rad/sec)
naz = Number of azimuth sectors
a = Lift curve slope of rotor airfoil (CL vs alpha)
Airfoil = Airfoil 1. HH-02 2. VR-12 3. NACA 0012
thetao = Collective pitch at .7 r/R (deg): ')/57.3
Afh = Aircraft equivalent flatplate area (ft²)
Afv = Vertical projected area (ft²)
Swing = Wing area, 0 if no wing (ft²)
bwing = Wing span (ft)
CLwing = Expected CL for the wing
CDwing = Wing profile drag coef (CDo)
ewing = Wing efficiency factor (e)
Shoriz = Horizontal tail area, 0 if none (ft²)
if Shoriz~=0,
 bhoriz = Horizontal tail span (ft)
CLhoriz = Expected CL for the horizontal tail
CDohoriz = Horizontal tail profile drag coef (CDo)
Svert = Vertical tail area, 0 if none (ft²)
if Svert~=0,
 bvert = Vertical tail span (ft)
 CLvert = Expected CL for the vertical tail
 CDovert = Vertical tail profile drag coef (CDo)
Taux = Auxiliary thrust (lbs)
tr = Blade chord taper ratio (tip/chord)
trst = Blade taper start position (r/R)

Stability & Control (with Tiltrotor) Routine

Main rotor

Ib = Blade flapping moment of inertia (slug ft²)
hmd = Hub height above reference datum/waterline (ft)
lmd = Hub fuselage station (ft)
ymd = Hub position right of buttline (ft)
im = Mast incidence (negative forward, deg)/57.3;
Kflpsprng = Hub flapping spring constant (ft-lbs/deg)*57.3;

Tail rotor

htd = Tail rotor height above reference datum/waterline (ft)
ltd = Tail rotor fuselage station (ft)
ytd = Tail rotor position right of buttline (ft)
bt = Number of tail rotor blades
cot = Tail rotor blade chord (ft)
Rt = Tail rotor blade radius (ft)
at = Average lift curve slope of tail rotor
ohmt = Rotational velocity of tail rotor (rad/sec)
Ibt = Tail rotor blade flapping moment of inertia (slug ft²)
delta3 = Delta-3 angle (deg)/57.3;
thetalt = Blade twist (deg)/57.3;

NOTAR

htnd = Height above reference datum/waterline (ft)
ltnd = Fuselage station (ft)
ytnd = Position right of buttline (ft)
dian = NOTAR boom diameter (ft)
swirl = Swirl angle at boom (deg)/57.3;
Ytmaxn = Maximum NOTAR thruster force (lbs)
lttnd = Thruster fuselage station reference (ft)

Tilt Rotor

lfd = Fuselage station of (fuselage) Center of Pressure (ft)
alplof = Fuselage angle @ zero lift (degrees) /57.3;
af = Lift curve slope of fuselage (1/rad)
cmof = Fus. mom. coef. @ zero alpha (ref. to Aw & cw)
cmalpf = Slope of fus. moment coef. wrt alpha curve (1/rad)
delih = Horizontal Tail Span Efficiency, (e) - 1;
epso = Downwash angle @ zero alpha (rad)
dclhddelh = Change in H-stab Cl wrt elevator angle (1/rad)
acw = Wing Aerodynamic Center location (% cw)
lambda = Wing sweep angle (deg)*pi/180;
dih = Wing Dihedral angle (deg)*pi/180;
cmow = Wing Moment Coeff @ zero lift
dclwddelf = Change in roll mom. coeff. wrt flaperon defl. (1/rad)

Vertical tail

hvd = Height above reference datum/waterline (ft)
lvd = Fuselage station (ft)
yvd = Position right of buttline (ft)
alplov = Zero lift angle for vertical tail (deg)/57.3;
clvertmax = Maximum Cl for vertical tail
qvq = Dynamic pressure ratio for tail (pg 489 Prouty)
av = Lift curve slope of vertical tail
crv = Vert. tail root chord (ft)
ctv = Vert. tail tip chord (ft)
delih=1/(input('Vert. tail span efficiency factor (e))-1;
cfcv = Rudder chord length (% cv)

Horizontal tail

hhd = Height above reference datum/waterline (ft)
lhd = Fuselage station (ft)

yhd = Position right of buttline
 alploh = Zero lift angle for horizontal tail (deg)/57.3;
 ih = Angle of incidence of horizontal tail (deg)/57.3;
 ah = Lift curve slope of horizontal tail
 qhq = Dynamic pressure ratio for tail (pg 489 Prouty)
 vhw1 = Rotor downwash ratio for h-tail (pg 489 Prouty)
 deysdalph = Fuselage downwash ratio for h-tail (pg 489 Prouty)

Wing

hwd = Height above reference datum/waterline (ft)
 lwd = Fuselage station (ft)
 ywd = Position right of buttline (ft)
 alplow = Zero lift angle for wing (deg)/57.3;
 iw = Angle of incidence of wing (deg)/57.3;
 aw = Lift curve slope of wing
 ctw = Tip cord (ft)
 crw = Root cord (ft)
 vww1 = Rotor downwash ratio for wing (pg 489 Prouty)
 detafdalpfw = Fuselage downwash ratio for wing (pg 489 Prouty)

CG location

zcg = CG height above reference datum/waterline (ft)
 xcg = CG Fuselage station (ft)
 ycg = CG position right of buttline (ft)

Fuselage moments of inertia/downwash parameter

Ixx = Ixx (slug ft²)
 Iyy = Iyy (slug ft²)
 Izz = Izz (slug ft²)
 Ixz = Ixz (slug ft²)
 vfv1 = Downwash ratio for fuselage (page 513 Prouty)

Rigging

db1mddele = Long cyclic pitch per inch defl (deg/in)/57.3;
 da1mddele = Lateral cyclic pitch per inch defl (deg/in)/57.3
 dthetomddelc = Collective pitch per inch defl (deg/in)/57.3

 if notar==0
 dthetotddelp = Tail rotor pitch change per inch defl
 or % twist (deg/in or deg/deg of twist)/57.3
 if notar==1
 sidearm = Max deflection of anti-torque from neutral for NOTAR,
 enter 1000 if using tail rotor (deg or inch travel)*2
 if ctail==1
 maxr = Displacement of anti-torque control until full rudder
 deflection (deg or inch travel)
 dclvddelp = Change in (side force) lift wrt rudder defl. (1/rad)

 if tltrotr==1
 ddeladlat = Aileron angle per inch defl (deg/in)/57.3;
 dthetomddelc = Collective thrust per inch defl (deg/in)/57.3;
 ddeledlong = Elevator angle per inch defl (deg/in)/57.3;
 ddelrddelp = Rudder angle per inch defl of pedals/57.3;

For a the state vector, $\mathbf{x} = [\Delta u \Delta w \Delta q \Delta \theta \Delta v \Delta p \Delta \phi \Delta r \Delta \Psi]^T$

$$A = \begin{bmatrix} \frac{X_u}{m} & \frac{X_w}{m} & \frac{X_q}{m} - w_0 & -g \cos \theta_0 & \frac{X_v}{m} & \frac{X_p}{m} & 0 & \frac{X_r}{m} + v_0 & 0 \\ \frac{Z_u}{m} & \frac{Z_w}{m} & \frac{Z_q}{m} + u_0 & -g \cos \phi_0 \sin \theta_0 & \frac{Z_v}{m} & \frac{Z_p}{m} - v_0 & -g \sin \phi_0 \cos \theta_0 & \frac{Z_r}{m} & 0 \\ \frac{M_u}{I_y} & \frac{M_w}{I_y} & \frac{M_q}{I_y} & 0 & \frac{M_v}{I_y} & \frac{M_p}{I_y} & 0 & \frac{M_r}{I_y} & 0 \\ 0 & 0 & \cos \phi_0 & 0 & 0 & 0 & 0 & -\sin \phi_0 & 0 \\ \frac{Y_u}{m} & \frac{Y_w}{m} & \frac{Y_q}{m} & -g \sin \phi_0 \sin \theta_0 & \frac{Y_v}{m} & \frac{Y_p}{m} + w_0 & -g \cos \phi_0 \cos \theta_0 & \frac{Y_r}{m} - u_0 & 0 \\ \frac{(I_z L_u + I_{xz} N_u)}{I_c} & \frac{(I_z L_w + I_{xz} N_w)}{I_c} & \frac{(I_z L_q + I_{xz} N_q)}{I_c} & 0 & \frac{(I_z L_v + I_{xz} N_v)}{I_c} & \frac{(I_z L_p + I_{xz} N_p)}{I_c} & 0 & \frac{(I_z L_r + I_{xz} N_r)}{I_c} & 0 \\ 0 & 0 & \sin \phi_0 \tan \theta_0 & 0 & 0 & 1 & 0 & \cos \phi_0 \tan \theta_0 & 0 \\ \frac{(I_{xz} L_u + I_x N_u)}{I_c} & \frac{(I_{xz} L_w + I_x N_w)}{I_c} & \frac{(I_{xz} L_q + I_x N_q)}{I_c} & 0 & \frac{(I_{xz} L_v + I_x N_v)}{I_c} & \frac{(I_{xz} L_p + I_x N_p)}{I_c} & 0 & \frac{(I_{xz} L_r + I_x N_r)}{I_c} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

where, $I_c = I_x I_z - (I_{xz})^2$

For the control vector, $\mathbf{u} = [\Delta \delta_e \Delta \delta_c \Delta \delta_a \Delta \delta_p]^T$
